

2 Regulatory Background

This section provides a list of documents that offer technical background, regulatory perspective, and guidance relevant to understanding and using bioavailability in risk assessment. This section also includes the information collected from state risk assessors and ITRC Bioavailability in Contaminated Soil (BCS) team members about the use of bioavailability in their states.

▼ [Read more](#)

Regulatory guidance is available for evaluating site-specific bioavailability in HHRAs; Table 2-1 summarizes several key guidance documents. These documents establish a broad precedent for incorporating bioavailability values into the risk assessment process, beginning with foundational documents such as USEPA’s 1989 ([USEPA 1989b](#)) *Risk Assessment Guidance for Superfund* (RAGS).

(USEPA and BARC 2008)	<i>Standard Operating Procedure for an In Vitro Bioaccessibility Assay for Lead in Soil</i>	

[Regulatory constraints](#) are also discussed in this guidance in the context of a site-specific decision to conduct a bioavailability assessment. The chemical-specific sections also include information about existing guidance.

2.1 Current Practices: Survey of State Regulators

▼ [Read more](#)

In October 2015, ITRC informally surveyed risk assessors in state regulatory agencies throughout the country to understand how bioavailability is used in **human health risk assessments** within their jurisdiction. The following questions were

asked:

- Does the state use bioavailability or relative bioavailability of contaminants in soil in risk assessments?
- If so, does the state have any guidance or policy regarding the development and application of bioavailability or RBA of contaminants in soil?

Responses were received from 14 individuals from 12 states. Additional information has been provided by state members of the BCS team for states that did not respond to the initial survey. Table 2-2 summarizes the information provided by respondents. The responses indicate that lead is the chemical for which site-specific RBA values are most often incorporated. The responses summarized in Table 2-2 should be interpreted as anecdotal experience of the individuals who responded rather than as the official position of the respective states. There also may be multiple programs within a state which have different experiences. These responses also often indicated emerging policy or precedents. The responses are included in [Detailed Survey Responses](#).

Table 2-2. Summary of current practices

State	Does your state use bioavailability?	Does the state have guidance or policy?
Alaska	Yes, with limitations.	The information is in our Risk Assessment Procedural Manual which is adopted in regulation.
California	Yes, in certain cases.	New guidance document for Arsenic, August 2016.
Florida	Florida is using an RBA of 0.33 for arsenic when calculating risk. Site-specific bioavailability evaluations have been completed for a small number of sites.	No official guidance.
Georgia	Yes, but only for human health risk evaluations and on a site-specific basis contingent upon the amount of well-supported and credible data provided.	Georgia has not yet issued guidance on bioavailability, but is in the process of updating its risk assessment guidance to clarify our current stance on bioavailability.
Kentucky	No, with the possible exception of lead.	Currently, no guidance or policy.
Massachusetts	We have allowed a relative bioavailability (RBA) approach at one site in Massachusetts for human health risks related to arsenic soil exposures.	We do not have a formal policy for RBA.
Michigan	Michigan DEQ used the IEUBK model which includes a default value for bioavailability of lead in soil, in developing the direct contact criteria for lead. MDEQ has allowed the use of site-specific RBA for arsenic or in vivo BA for dioxin.	No state guidance or policy; however, MDEQ uses USEPA guidance on bioavailability or RBA.
Missouri	Yes, bioavailability has been used in soil risk assessments prepared by USEPA on Superfund sites in Missouri (and reviewed by Missouri DNR and DHSS).	Currently no guidance or policy.
Montana	Montana uses RBA for lead and arsenic and we use USEPA guidance. If it were proposed for other contaminants, we would consider it.	
New York	In the Department of Health, depending upon the purpose of the evaluation and the amount and quality of information available to us, we would either implement a generic approach, or tailor the evaluation as warranted and supportable. In the Department of Environmental Conservation cleanup program, site-specific risk assessments are not commonly used when determining remedies for site.	No.

State	Does your state use bioavailability?	Does the state have guidance or policy?
Oklahoma	It is not common for us to run into this issue, we can look at bioavailability on a site-specific basis, but it needs to be well supported.	We do not have specific guidance on this issue.
Oregon	On a couple of projects in the Oregon Department of Environmental Quality's Cleanup Program, we used the results of laboratory relative bioavailability studies. In both cases, arsenic was the chemical of interest. These studies were done on a site-specific basis.	We do not have state guidance on RBA.
Pennsylvania	Generally, what we tell remediators is that they should assume 100% bioavailability unless they can demonstrate a site-specific value is more accurate. Remediators can use USEPA's default value of 60% for arsenic, but a site-specific number using an approved USEPA method is preferred.	We do not have specific guidance yet for how to handle bioavailability of contaminants in soil.
Utah	We have used site specific lead and arsenic bioavailability estimates in the soil risk assessments for the CERCLA activities.	The State of Utah has not developed guidance and rely on USEPA guidance.
Virginia	Bioavailability is not used, except for USEPA value for arsenic.	There is no guidance or similar on bioavailability.
Washington State	For mixtures of dioxins and furans, we allow the use of 60% bioavailability from soil. For lead, where we have set remediation levels using the IEUBK model, the model default of 60% was used. For arsenic, we use 100 % bioavailability.
